

Semester Project Reflection – Community Science Museum Website

In this project, I designed and developed a website for a community science museum. I first created a high-fidelity prototype in Figma to plan the layout, colours, and user experience, and then built the site using code. I organized my work using a Kanban board and managed versions through a GitHub repository.

To manage the project, I broke the work into small tasks and moved them through stages like planning, design, development, and testing. This helped me stay organized and made the process feel more manageable. Using GitHub also helped me keep track of changes and avoid losing work.

What worked well was designing before coding. Having a clear prototype made development easier because I already knew how everything should look and function. The Kanban board also helped me stay focused and see my progress.

One challenge was turning the design into a responsive website that worked on different screen sizes. I solved this by testing often and adjusting the layout and code until it behaved the way I wanted. I also had to balance visual design with performance, which meant simplifying some elements.

This project helped me adapt my existing HTML, CSS, and design skills to new tools like Figma, GitHub, and structured workflow methods. I learned how professional projects are planned and organized, not just built.

I completed all parts of the project myself, which helped me understand the full process from idea to finished product.

Overall, this project gave me practical experience in both design and development, and it showed me the importance of planning, organization, and continuous improvement.
